AB A review with 173 refs. Plant systems utilize a diverse array of cytochrome P 450 monooxygenases (P450s) in their biosynthetic and detoxification pathways. The classic forms of these enzymes are heme dependent mixed function oxidases that utilize NADPH or NADH and mol. oxygen to produce functionalized organic products. The nonclassical forms are monooxygenases that either do not utilize flavoproteins for dioxygen activation or fail to incorporate mol. oxygen into their final product. Biosynthetic P450s play paramount roles in the synthesis of lignin intermediates, sterols, **terpenes**, flavonoids, isoflavonoids, furanocoumarins, and a variety of other secondary plant products. Other catabolic P450s metabolize toxic herbicides and insecticides into nontoxic products or, conversely, activate nontoxic substances into toxic products. Biochem. and mol. characterizations on a number of plant P450s have indicated that the relationships between these heme proteins and their substrates are at least as complex as those that exist in mammalian systems. Examples now exist of plant P450s that metabolize: a narrow range of substrates to yield different products, a single substrate to yield different products, multiple substrates to yield the same product, or a single substrate sequentially to yield discrete intermediates in the biosynthesis of a single product. Extensive divergence of catalytic site as well as noncatalytic site residues accounts for the high degree of primary structure variation in the P 450 gene superfamily and the diverse array of substrates synthesized and/or detoxified by these proteins. Classic P450s still retain a highly conserved F--G-R-C-G motif in their catalytic site and conserved amino acids in their oxygen binding pocket; nonclassical P450s diverge at several of these positions. A broad range of cloning and transient expression strategies are suitable for plant P 450 studies and these have allowed for the isolation and characterization of a number of P 450 cDNAs and genes. Because many of these sequences have been cloned only recently, much remains to be learned about the substrate specificities of P 450 reactions in plants and the mechanisms by which their genes are regulated.

AB The structure, properties, and reaction states of the 3 pure proteins of the cytochrome **P450 monooxygenase** system, rubredoxin, cytochrome b5, and putidaredoxin, which accomplish a 2-electron reduction of O and stereoselective conversion of specific methylene groups of certain related **terpenes** to secondary alcs. are considered. These proteins are composed of a single polypeptide chain, and each carries one mol. of its prosthetic group. Both rubredoxin and cytochrome b5 oxidize ferrous P450cam and, much more slowly, the ferrous oxy form, but neither reduces the former. The general reactions of putidaredoxin, reduction and reoxdn., are given in diagrams.
